# Our objectives:

1. How do we evaluate how good our model is at prediction?
2. What are the theoretical properties of our model?

**How do we evaluate how good our model is at prediction?**

---

# Measuring the Quality of Fit

Think back to our first in-class activity. How did we quantify how well our model is able to predict patient satisfaction?

We needed some way to measure how well our regression model's predicted values ( $\hat{Y}$ ) (match the actual observed response ( $Y$ )).

# Mean squared error (MSE)

$$Y = f(X) + \epsilon$$

**Problem:**  $f(x)$  is unknown.

**Goal:** Estimate  $f(x)$  from the data:  $\hat{f}(x)$ .

We need some way to measure how well a regression model actually matches the observed data.

In the regression setting, the most commonly-used measure is the mean squared error (MSE), given by

$$\text{MSE} = \frac{1}{n} \sum_{i=1}^n \left( y_i - \hat{f}(x_i) \right)^2 .$$

# Training MSE

Training data set is the data you used to build your model. The MSE evaluated on this data set is referred to as the training MSE.

Suppose  $(x_i, y_i), i = 1, \dots, n$  represents our training data.  $\hat{f}$  is estimated from training data and then our training MSE is:

$$\frac{1}{n} \sum_{i=1}^n \left( y_i - \hat{f}(x_i) \right)^2 .$$

# Training MSE

In general, we do not really care how well the method works training on the training data.

Rather, we are interested in the accuracy of the predictions that we obtain when we apply our model to previously *unseen test data*.

# Test MSE

Test data set is some previously unseen data that were not used to train the model. The MSE evaluated on the test set is referred to as the test MSE.

Suppose  $(x'_i, y'_i), i = 1, \dots, n$  represents our test data. Then our test MSE is:

$$\frac{1}{n} \sum_{i=1}^n \left( y'_i - \hat{f}(x'_i) \right)^2 .$$

# Training MSE vs. Test MSE

- As we'll see in the next module, the training MSE and test MSE behave very differently.
- A model that results in a small training MSE will not necessarily result in a small test MSE.
- Our goal in prediction is to select a method that minimizes the test MSE. Low training MSE does not imply low test MSE.

**What are the theoretical properties of our model?**

# Properties of least square estimators

- Remember in real applications, the true parameters  $\beta_0, \beta_1, \dots, \beta_p$  are unknown to us.
- Ideally, we hope our least square estimates  $\hat{\beta}_0, \hat{\beta}_1, \dots, \hat{\beta}_p$  are close to the true values of  $\beta_0, \beta_1, \dots, \beta_p$ .
- We can quantify how 'close' our estimates are to the truth using the following concepts:
  - Bias
  - Standard error

Population Variance	Sample Variance
$\sigma^2 = \frac{\sum_{i=1}^N (x_i - \mu)^2}{N}$ <p> <math>\sigma^2</math> = population variance  <math>x_i</math> = value of <math>i^{th}</math> element  <math>\mu</math> = population mean  <math>N</math> = population size </p>	$s^2 = \frac{\sum_{i=1}^n (x_i - \bar{x})^2}{n-1}$ <p> <math>s^2</math> = sample variance  <math>x_i</math> = value of <math>i^{th}</math> element  <math>\bar{x}</math> = sample mean  <math>n</math> = sample size </p>

Low Bias

High Bias

# Properties of least square estimators

How good are our estimates?

# Properties of least square estimators

# Accuracy of $\beta$

- The unbiasedness property tell us that the average of our estimates from many many datasets will be very close to the true population parameter  $\beta$ .
- But we don't have access to many many datasets. For a particular data set, the single estimates  $\hat{\beta}_0, \hat{\beta}_1, \dots, \hat{\beta}_p$  may be a substantial underestimate or overestimate of the true  $\beta_0, \beta_1, \dots, \beta_p$ .
- How far off will our single estimate  $\hat{\beta}_0, \hat{\beta}_1, \dots, \hat{\beta}_p$  be?

# Accuracy of $\beta$

# Accuracy of $\beta$
